Lab 2: Agile Backlog Creation & Sprint Simulation in Jira

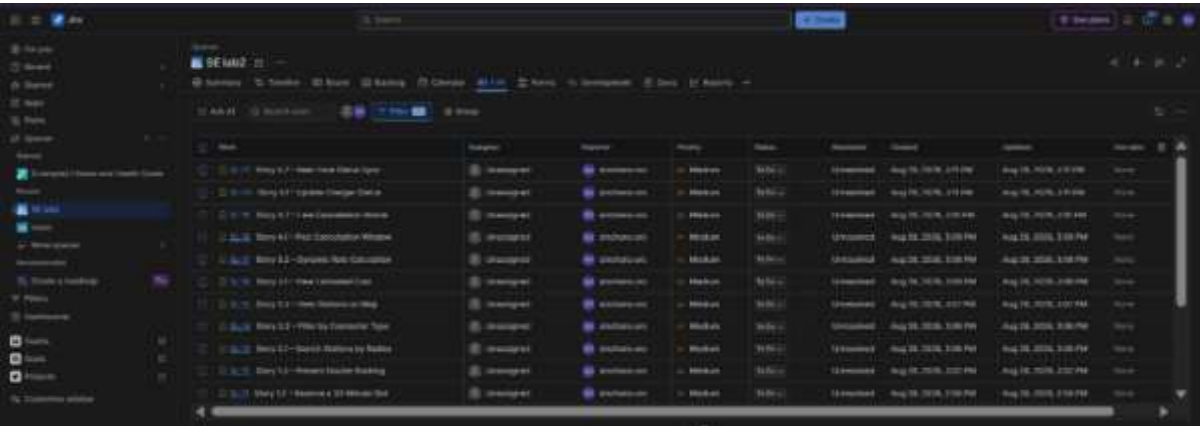

Problem Statement #21 — EV Charging Station Reservation System

Reflection Questions

1. Did your estimations reflect the actual effort?

Not meaningfully, since no actual development work was done in this lab. Story points were assigned to a couple of stories (e.g., 3 and 5) based on how complex they looked on paper, but because the "work" was only ever moved between columns manually rather than actually built, there was no real effort to compare the estimate against. The exercise showed us how to assign and read story points in Jira, but it did not test whether our estimates were accurate.

2. Was your backlog well-prioritized?

Yes, to the extent the lab required. We carried over the High/Medium priority split from our Lab 1 functional requirements onto the corresponding Epics and Stories (Epics 1–3 as High, Epics 4–5 as Medium), so the backlog reflects which parts of the EV charging system matter most (reservation and search) versus supporting features (cancellation, operator status updates).

3. How did your simulated sprint align with your plan?

Since this lab was meant to teach the Jira workflow rather than run a full sprint, we only pulled one or two stories into Sprint 1 and moved them straight through To Do, In Progress, and Done to demonstrate the mechanics, instead of executing a full week-long sprint with the whole backlog. So

the "plan" was really just to learn the tool, and the simulated sprint matched that limited scope — we did not attempt to plan or complete all 11 backlog stories.

4. What insights did the burndown chart give about your team's capacity?

Not much in terms of real capacity planning, because only one story with a small point value was in the sprint and it was marked Done almost immediately. The Remaining Work line drops to zero right at the start instead of trailing off over the week, and the Burnup report similarly shows Completed Work reaching total scope almost instantly. This tells us the chart is working correctly and reading our data, but with this little data in a single-person simulated sprint, it cannot say anything real about team velocity or capacity — that would only become meaningful with a full backlog worked on by an actual team over the full sprint duration.
